

Project Requirement Analysis Phase

Customer Journey Map

Date	01 October 2026
Team ID	SWTID-2026-7951
Project Name	Script-Controlled ACL – Restrict Record Access Based on Field Value
Maximum Marks	4 Marks

Scenario:

A branch user or administrator accesses a record in the ServiceNow application. The system evaluates the scripted ACL before allowing the record to be viewed.

The supplied journey-map template organizes the experience around steps, interactions, goals & motivations, positive moments, negative moments and areas of opportunity. [filecite?turn1file0?L3-L27?](#)

Steps	Interactions	Goals & Motivations	Positive Moments	Negative Moments	Areas of Opportunity
Login / Enter	User opens ServiceNow and signs in using their account.	Help me securely enter the system with my correct user identity.	Authentication is straightforward; the system knows the current user.	Incorrect credentials or unclear access may delay the task.	Provide clear login feedback and ensure the current user/branch context is available to the ACL.
Open Records	User navigates to the relevant table/list and searches for a record.	Help me find the record needed for my work.	Relevant records can be located quickly.	A user may encounter records that they are not permitted to view if controls are weak.	Apply record-level security consistently rather than relying only on list visibility.
Select Record	User opens a record containing a Branch value such as EEE.	Help me view the record only when I am authorized.	The system can automatically evaluate the access rule.	Access may be confusing if the reason for denial is not clear.	Use a scripted ACL that checks the record Branch against the user's authorized branch.
ACL Evaluation	The ACL obtains the logged-in user context and evaluates the Branch field.	Help me avoid unauthorized data access.	Access decisions are automatic and consistent.	Incorrect script logic could either expose records or block valid users.	Keep the script simple, testable and explicitly handle administrator access.
Allow / Deny	EEE user receives the EEE record; unauthorized users are denied; administrators retain access.	Help me complete my task without exposing restricted data.	Authorized access is immediate; administrators can manage all records.	Unexpected denial can interrupt work; unexpected access creates a security concern.	Provide clear access-denied handling and test EEE, non-EEE and admin scenarios.
Complete Task	User continues work or returns to the record list.	Help me finish my work confidently and securely.	The user can continue without manually checking permissions.	Repeated access problems may reduce trust in the system.	Log or document access-control behaviour and maintain the rule as branches change.

Customer Journey Map

Project: Script-Controlled ACL - Restrict Record Access Based on Field Value

	 Awareness Recognizes the need for access control	 Discover Explores options to solve the problem	 Plan Defines requirements and design	 Build Configures ACL with script logic	 Test Validates the access rules	 Deploy Implements in production	 Use End users interact with the system	 Maintain Monitors and improves over time
 Steps What does the customer do at this stage?	Identifies that some records should be restricted based on a field value	Searches for solutions and learns about script-controlled ACL	Defines fields, user roles and access rules to be implemented	Creates and configures ACL with script conditions	Tests access for different users and field values	Moves the solution to production	Uses the application to work with restricted and non-restricted records	Monitors access logs and updates rules when needed
 Interactions What interactions do they have with the system or team?	Discusses with stakeholders and understands the access requirements	Reads documentation, community articles and examples	Works with admins and stakeholders to finalize the design	Uses System Security > ACL and writes script conditions	Uses different user roles to verify access (create, read, update, delete)	Updates the application in production and communicates to users	Logs in as a user and tries to view or modify records	Reviews logs, user feedback and makes improvements
 Goals & motivations What are they trying to achieve?	Ensure sensitive records are secure	Find the best approach to restrict access based on field value	Create clear requirements and rules for different roles	Implement working script-controlled ACL	Confirm that access is correctly restricted for all scenarios	Roll out the solution without issues	Access only the records they are authorized to see	Keep the access rules up to date and secure
 Positive moments What makes the customer feel satisfied or happy?	Understands the business need clearly	Finds helpful documentation and samples	Gets approval from stakeholders	Script ACL works as expected	Access is correctly restricted for all users	Successful deployment	Can easily work with the records they have access to	System remains secure and users are satisfied
 Negative moments What frustrates or confuses them?	Unclear which records need to be restricted	Confusing information or too many options	Changing requirements from stakeholders	Script not working as expected or syntax errors	Access is still access restricted records due to logic issues	Deployment errors or missing updates	Access denied unexpectedly or cannot find records	Need to frequently update rules due to new use cases
 Areas of opportunity How might we improve this stage?	Provide clear examples of use cases	Create simple guides and templates for script-controlled ACL	Use a checklist for requirements and field values	Provide script samples and best practices	Create a test case list for different user roles and field values	Use a deployment checklist and rollback plan	Give clear error messages and help documentation	Set up monitoring and regular reviews of access rules
